Tasks:

- ☑ Member 1: Introduction and research framing - LOPEZ

Background, problem statement, objectives, research question, significance, and scope

- ☐ Member 2: Related literature: Philippine studies - ESPARTINAS

PIDS, CitiSense, government social media sentiment analysis

- ☐ Member 3: Related literature: NLP studies - CASILEN

Actionability detection, speech-act classification, code-switching, and research gap

- ☐ Member 4: Data collection, scraping, and annotation - MALASAN

Identify official government pages, collect comments using an authorized method, clean the dataset (remove exact duplicates and spam), anonymize data, manually annotate comments (everyone will help w this) Tho if there's an accurate auto annotator that can help, go.

- ☐ Member 5: Model development and evaluation - BAG-EO

Implement TF-IDF + Logistic Regression, add linguistic features, train both models, and compare results

- ☐ Member 6: Results, conclusion, and final editing - AGUSTIN

Interpret model results, write Results and Discussion, write the conclusion, and integrate the paper

Proposed Research:
"Detecting Actionable Suggestions in Filipino-English Code-Switched Government Social Media Comments"

This study aims to develop a machine-learning model that identifies actionable suggestions and requests in public Facebook comments on selected Philippine national government agencies' posts. Unlike sentiment analysis, which classifies comments as positive, negative, or neutral, our study focuses on whether citizens propose specific actions or request government responses.

For example, "Ang pangit ng kalsada namin" expresses a complaint, while "Please repair the damaged road in our barangay" requests a specific action. Our goal is to automatically distinguish actionable feedback from other comments written in Filipino, English, or a mixture of both.

Previous studies, including Philippine government-related social media sentiment analysis, have examined public opinions and reactions. However, sentiment does not necessarily indicate whether a comment contains a proposed solution or actionable request.

This study will investigate whether adding suggestion-related linguistic features improves the detection of actionable suggestions and requests in Filipino-English code-switched government social media comments.

Research Question: Does incorporating suggestion-related linguistic features improve the detection of actionable suggestions and requests compared with a TF-IDF and Logistic Regression baseline?

Data Collection: Obtain hundreds (up to member 4) of usable comments from selected national government Facebook pages, subject to authorized data access and availability.
Annotation: Label each comment as either actionable suggestion/request or other comment. Use clear annotation guidelines and human verification.
Model Development: Build two models:
(1) TF-IDF + Logistic Regression as the baseline, and (2) the same model with additional linguistic features such as "please," "dapat," "sana," and "paki-."
Evaluation: Compare both models using precision, recall, F1-score, macro-F1, and a confusion matrix on the same held-out test dataset.

The study will produce a labeled dataset, two trained classification models, and an empirical comparison showing whether suggestion-related linguistic features improve detection performance. The findings may inform future tools for organizing citizen feedback, although the study will not measure government responsiveness or actual policy outcomes.
